COMP 322

Organization of a Distributed-Memory Multiprocessor

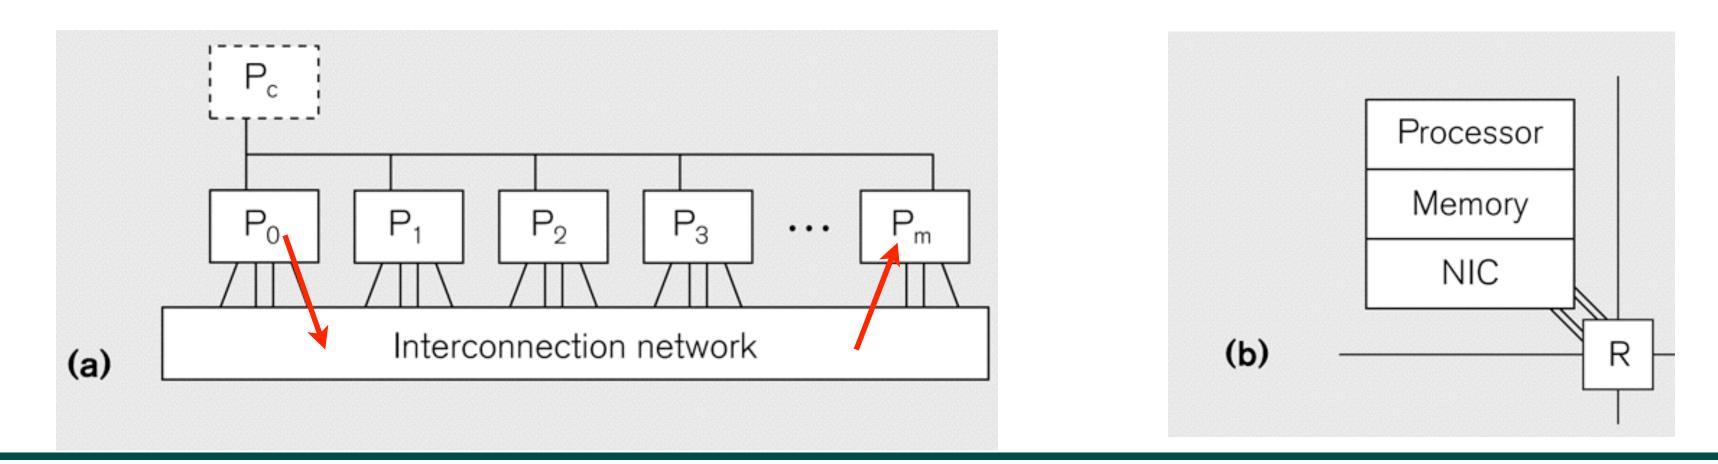

Figure (a)

- Host node (P_c) connected to a cluster of processor nodes ($P_0 \dots P_m$)
- Processors $P_0 \dots P_m$ communicate via an interconnection network which could be standard TCP/IP (e.g., for Map-Reduce) or specialized for high performance communication (e.g., for scientific computing)

Figure (b)

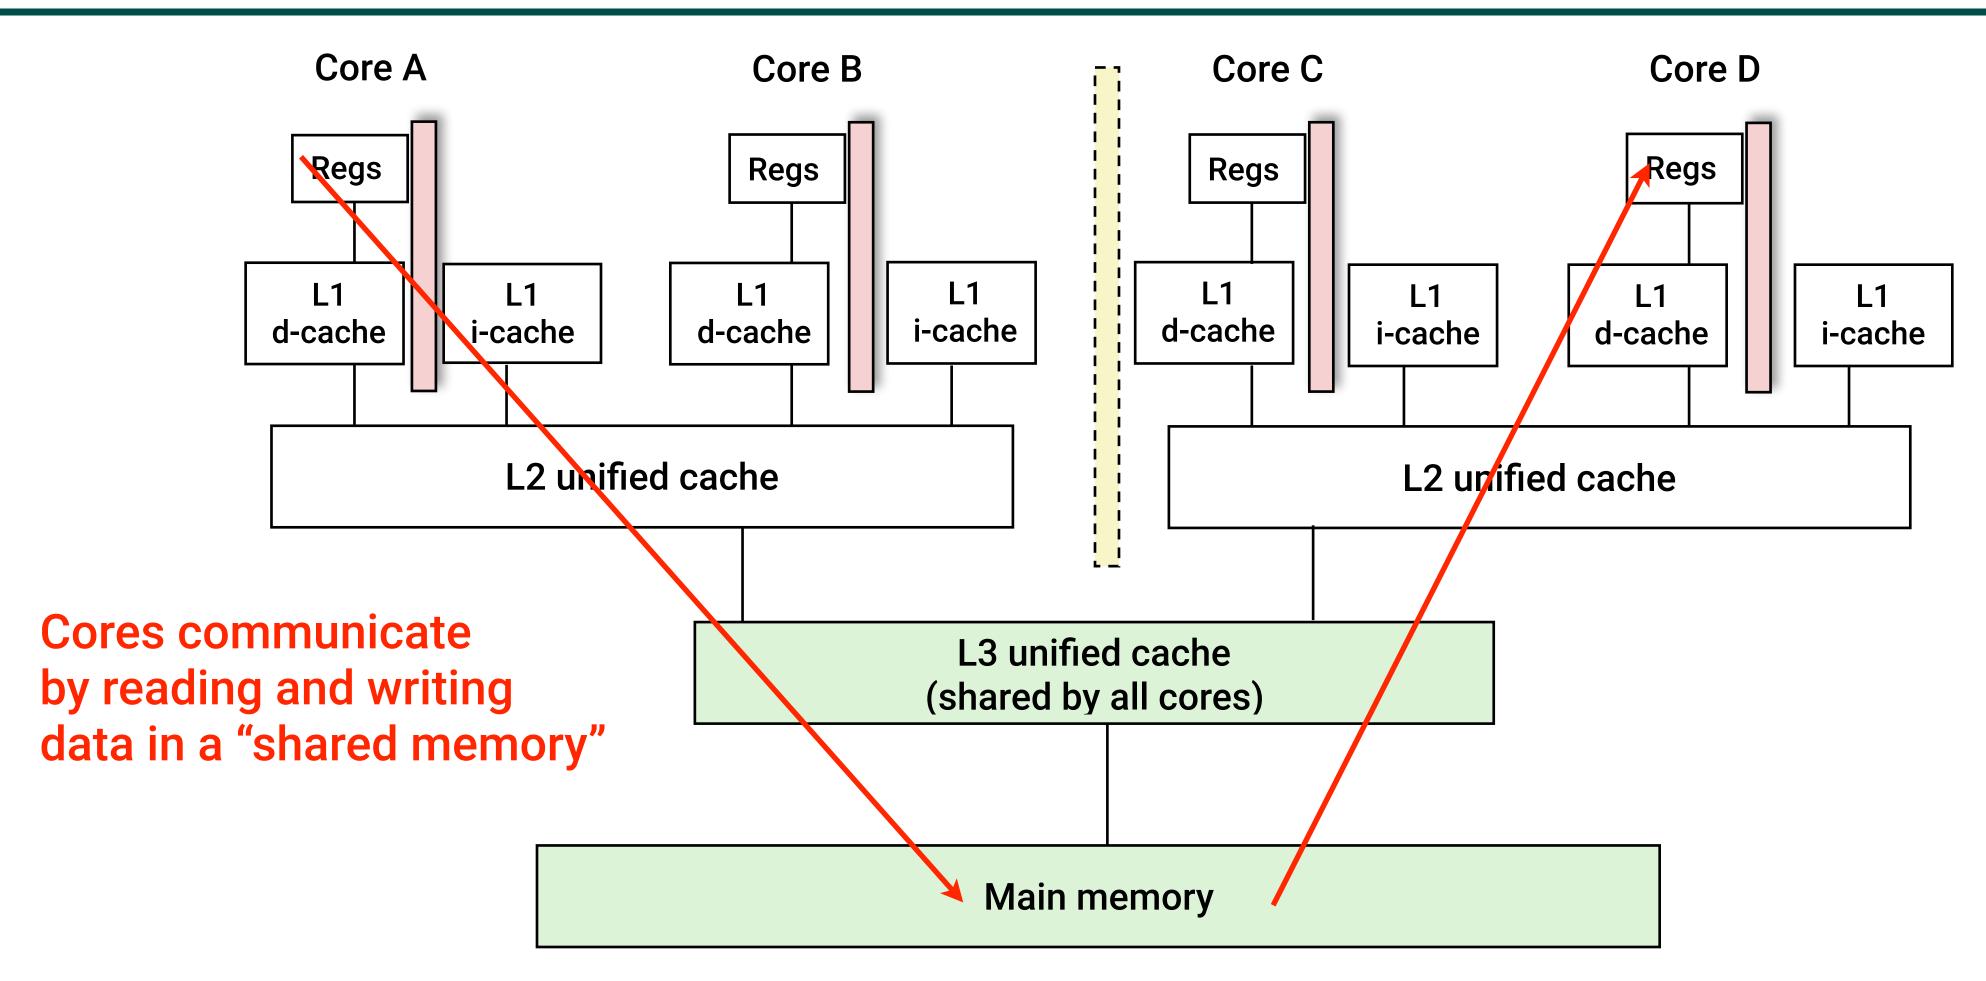

Each processor node consists of a processor, memory, and a Network Interface Card (NIC) connected to \bullet a router node (R) in the interconnect

Processors communicate by sending messages via an interconnect

Organization of a Shared-Memory Multicore Symmetric Multiprocessor (SMP)

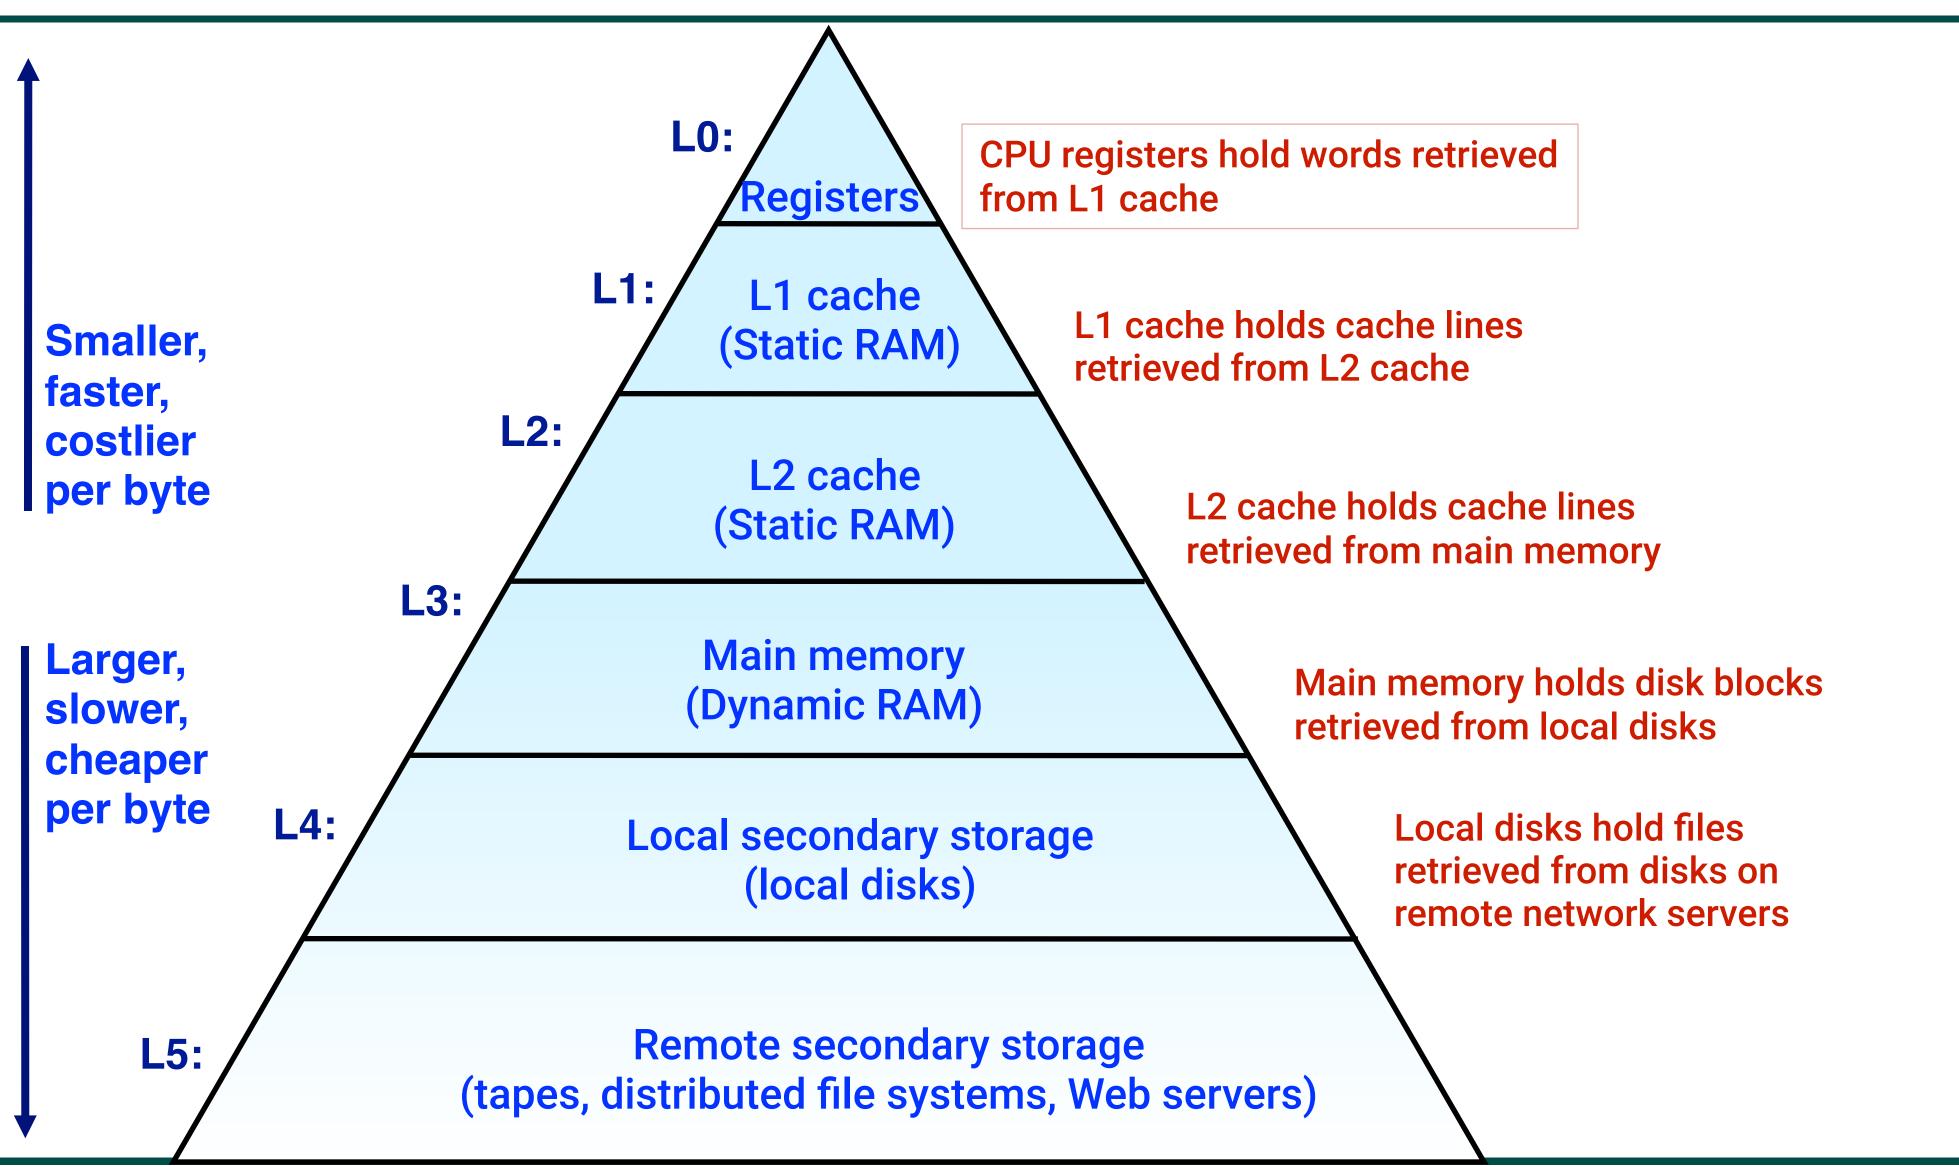

Memory hierarchy for a single Intel Xeon (Nehalem) Quad-core processor chip ${\color{black}\bullet}$

- A NOTS node contains TWO 8-core or 12-core E5-2650 v2 lvy Bridge chips, for a total of 16 or 24 cores

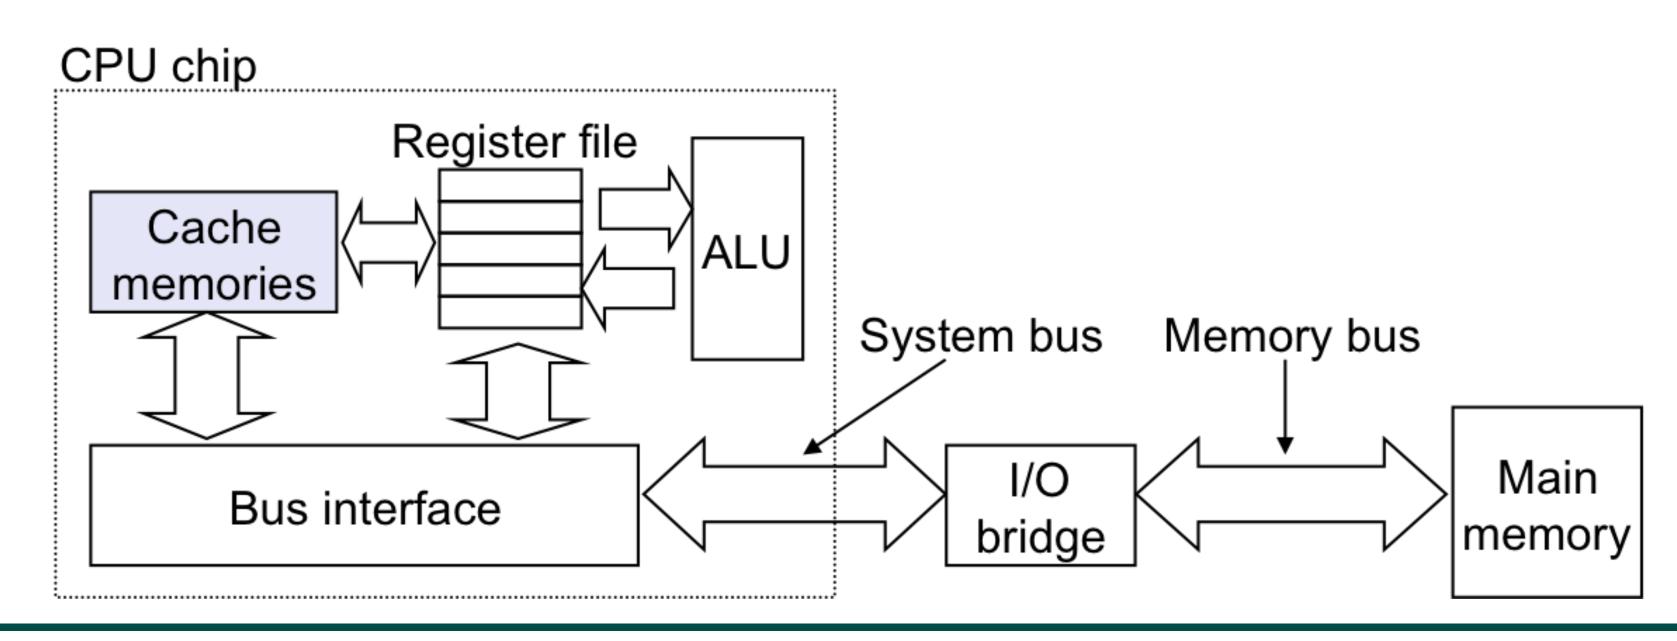

What is the cost of a Memory Access? **An example Memory Hierarchy**

- Cache memories are small, fast SRAM-based memories managed automatically in hardware. -Hold frequently accessed blocks of main memory
- CPU looks first for data in caches (e.g., L1, L2, and L3), then in main memory.
- Typical system structure:

Cache Memories

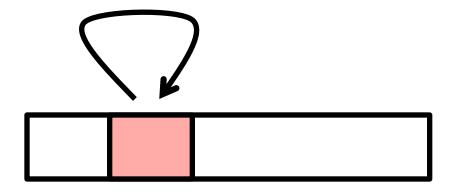

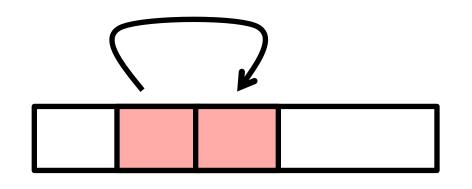

Principle of Locality:

-Empirical observation: Programs tend to use data and instructions with addresses near or equal to those they have used recently

- **Temporal locality:**
 - Recently referenced items are likely to be referenced again in the near future
- **Spatial locality:** •
 - Items with nearby addresses tend to be referenced close together in time
 - A Java programmer can only influence spatial locality at the intra-object level

The garbage collector and memory management system determines inter-object placement

Locality Example

sum = 0;return sum;

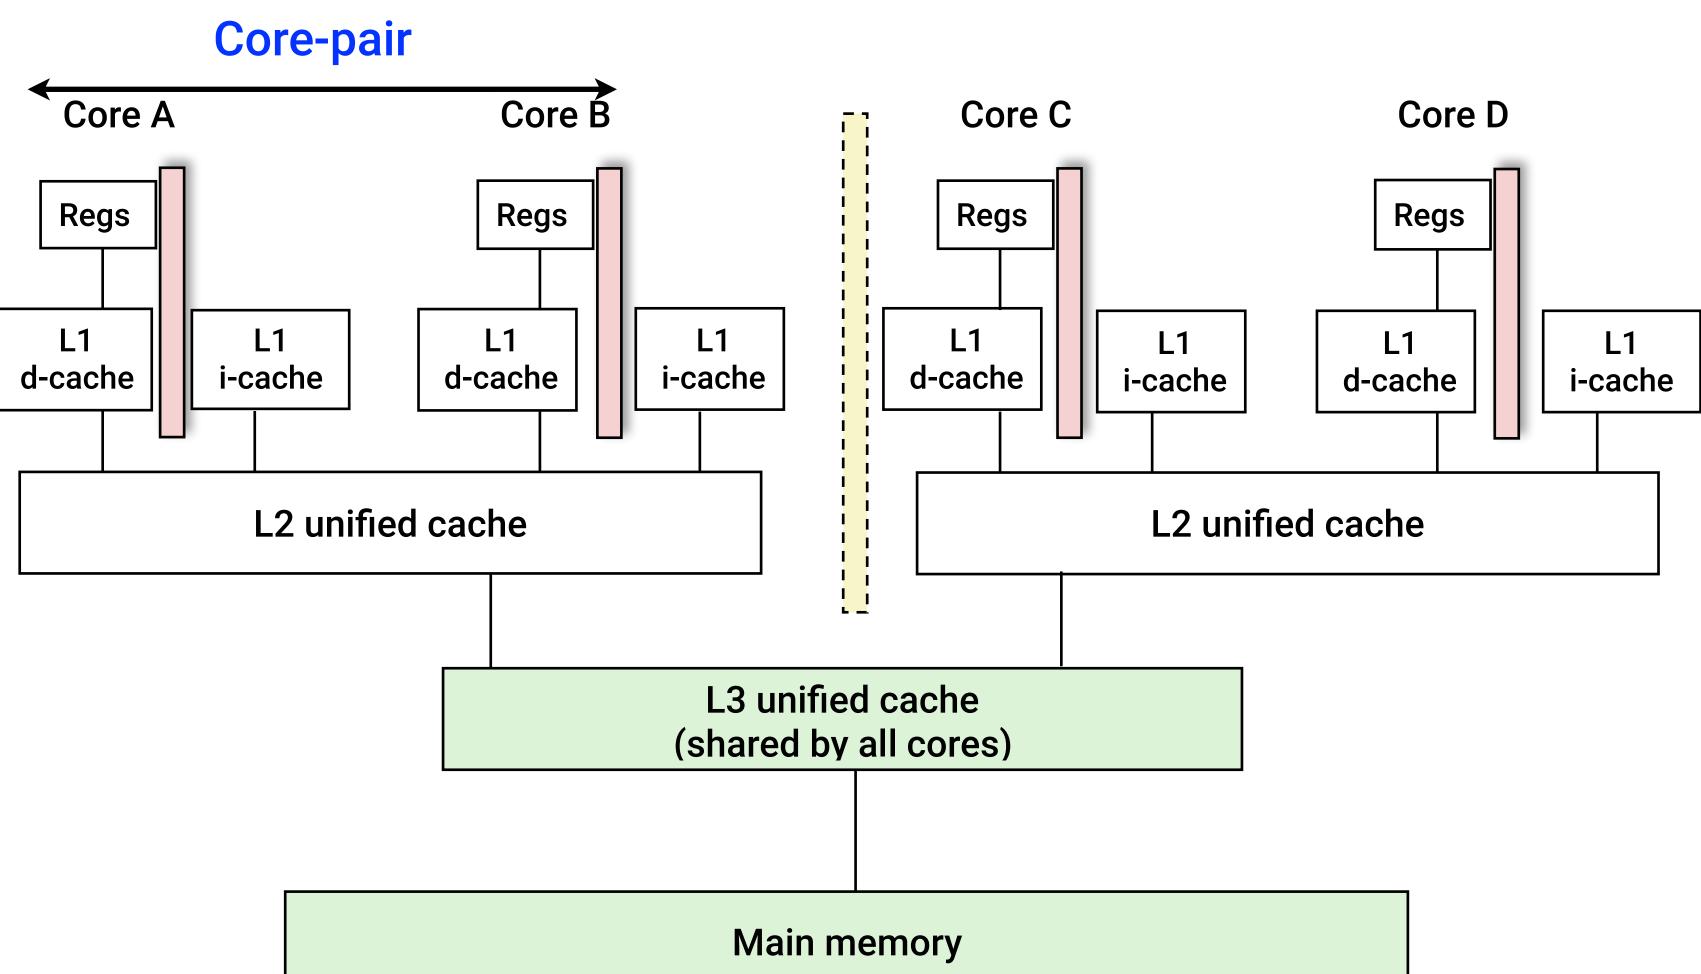

- Data references
 - Reference array elements in succession (stride-1 reference pattern).
 - Reference variable sum each iteration.
- Instruction references
 - Reference instructions in sequence.
 - Cycle through loop repeatedly.

for (i = 0; i < n; i++) sum += a[i];

Memory Hierarchy in a Multicore Processor

Memory hierarchy for a single Intel Xeon (Nehalem) Quad-core processor chip lacksquare

Programmer Control of Task Assignment to Processors

- The parallel programming constructs that we've studied thus far result in tasks that are assigned to processors dynamically by the HJ runtime system Programmer does not worry about task assignment details
- Sometimes, programmer control of task assignment can lead to significant \bullet performance advantages due to improved locality
- Motivation for HJ "places" \bullet
 - Provide the programmer a mechanism to restrict task execution to a subset of processors for improved locality

HJ programmer defines mapping from HJ tasks to set of places

HJ runtime defines mapping from places to one or more worker Java threads per place

The API calls

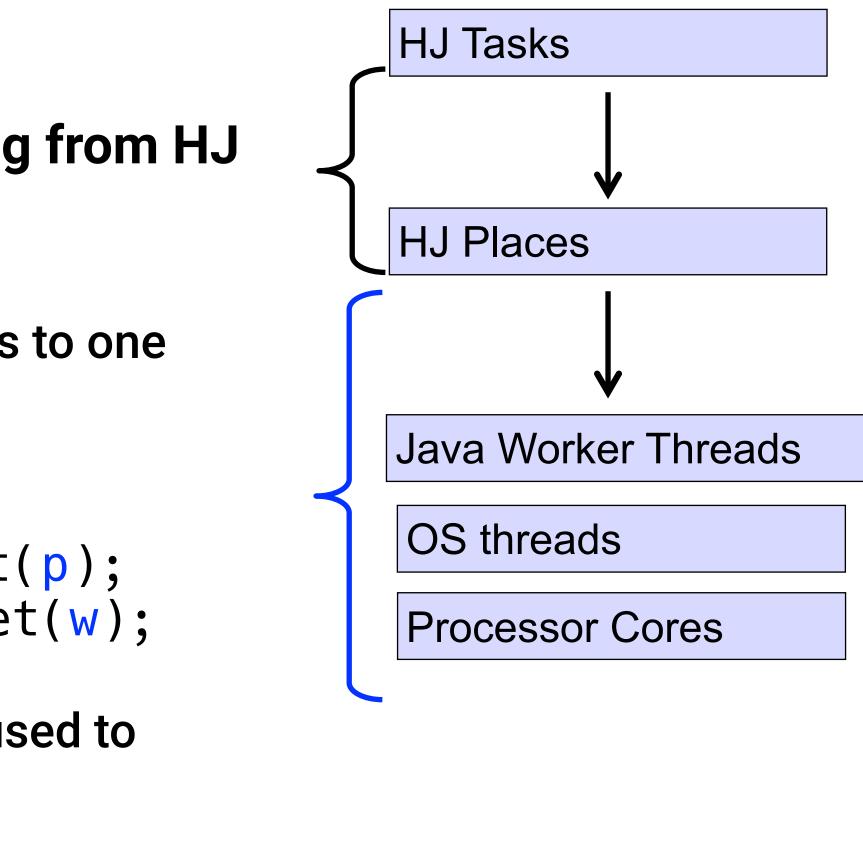

HjSystemProperty.numPlaces.set(p); HjSystemProperty.numWorkers.set(w);

when executing an HJ program can be used to specify

p, the number of places

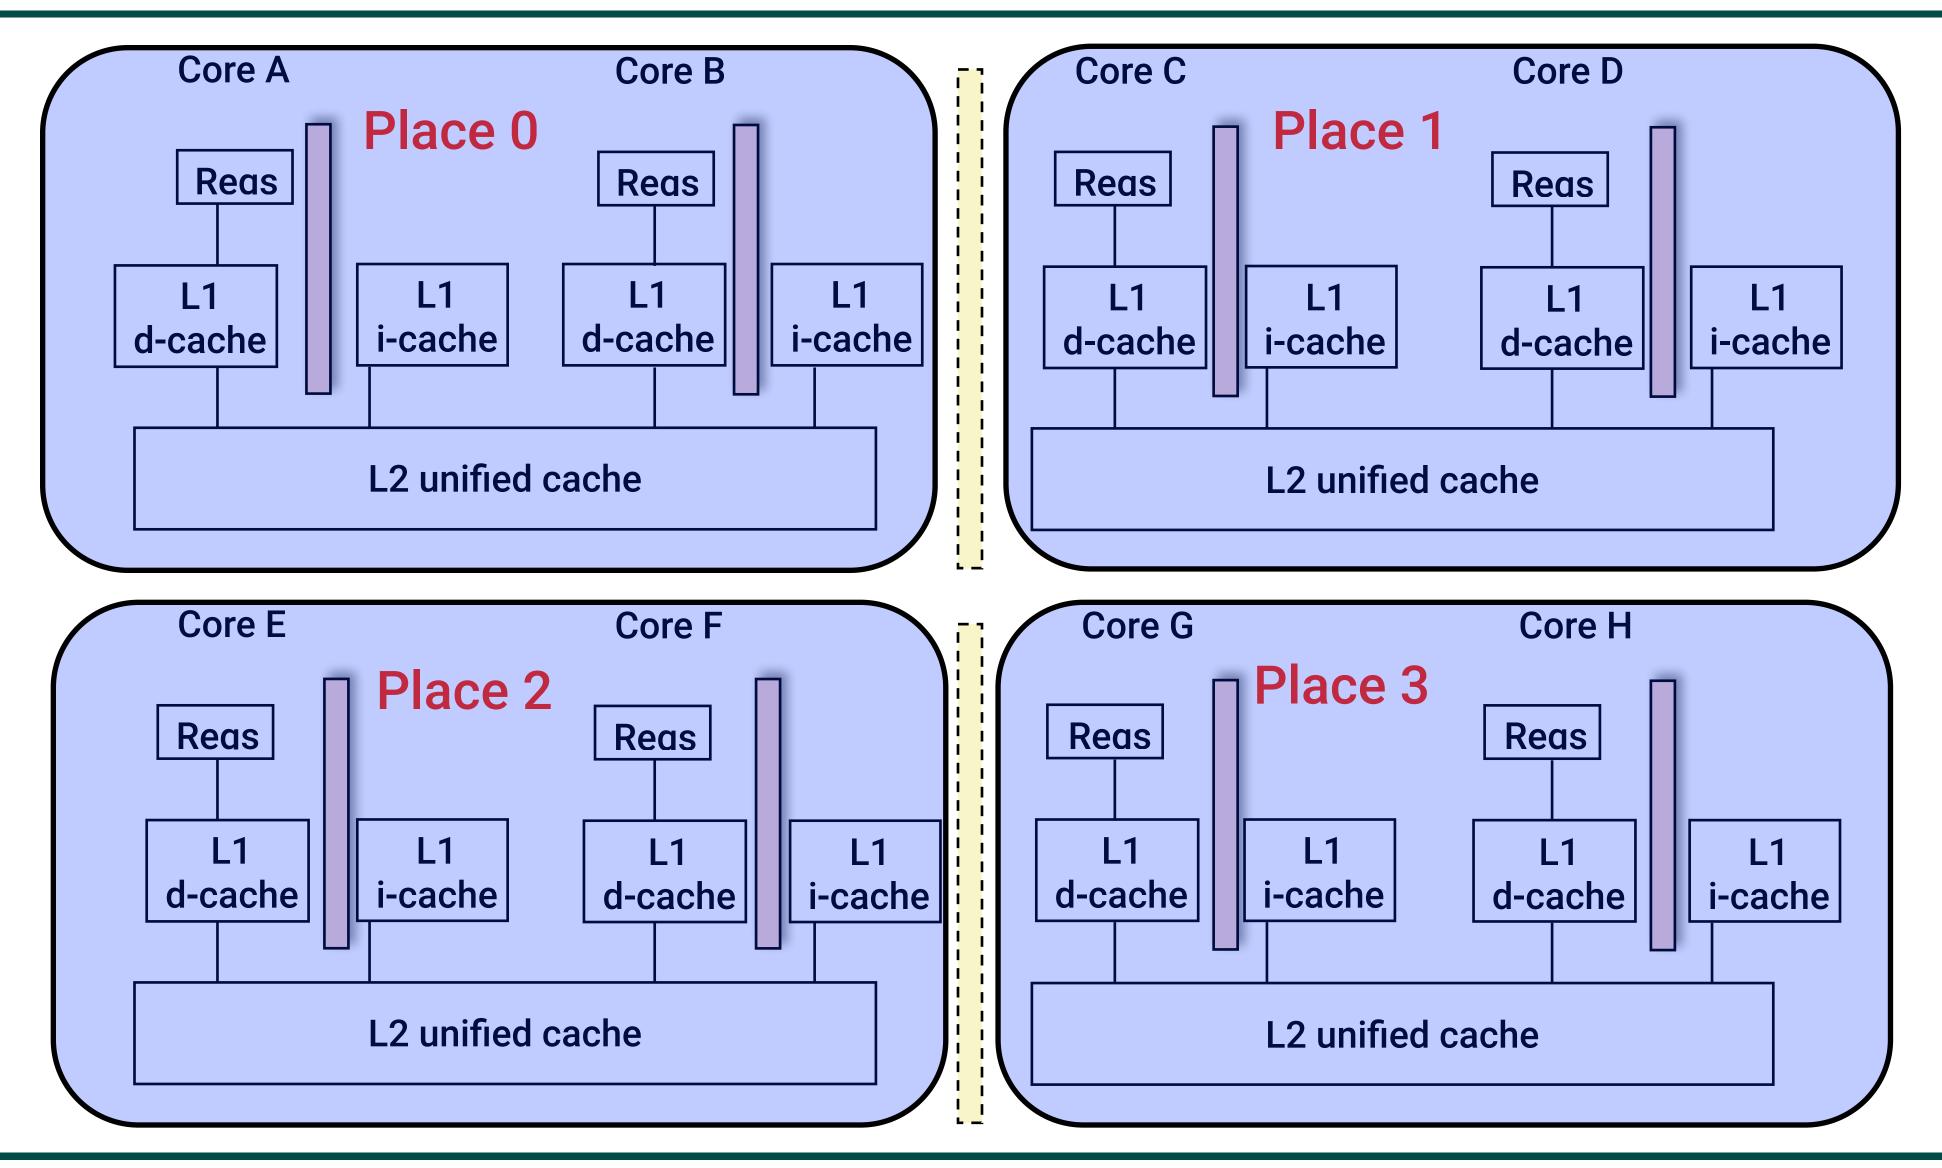

w, the number of worker threads per place we will abbreviate this as p:w

Places in HJlib

Example of 4:2 option on an 8-core node (4 places w/ 2 workers per place)

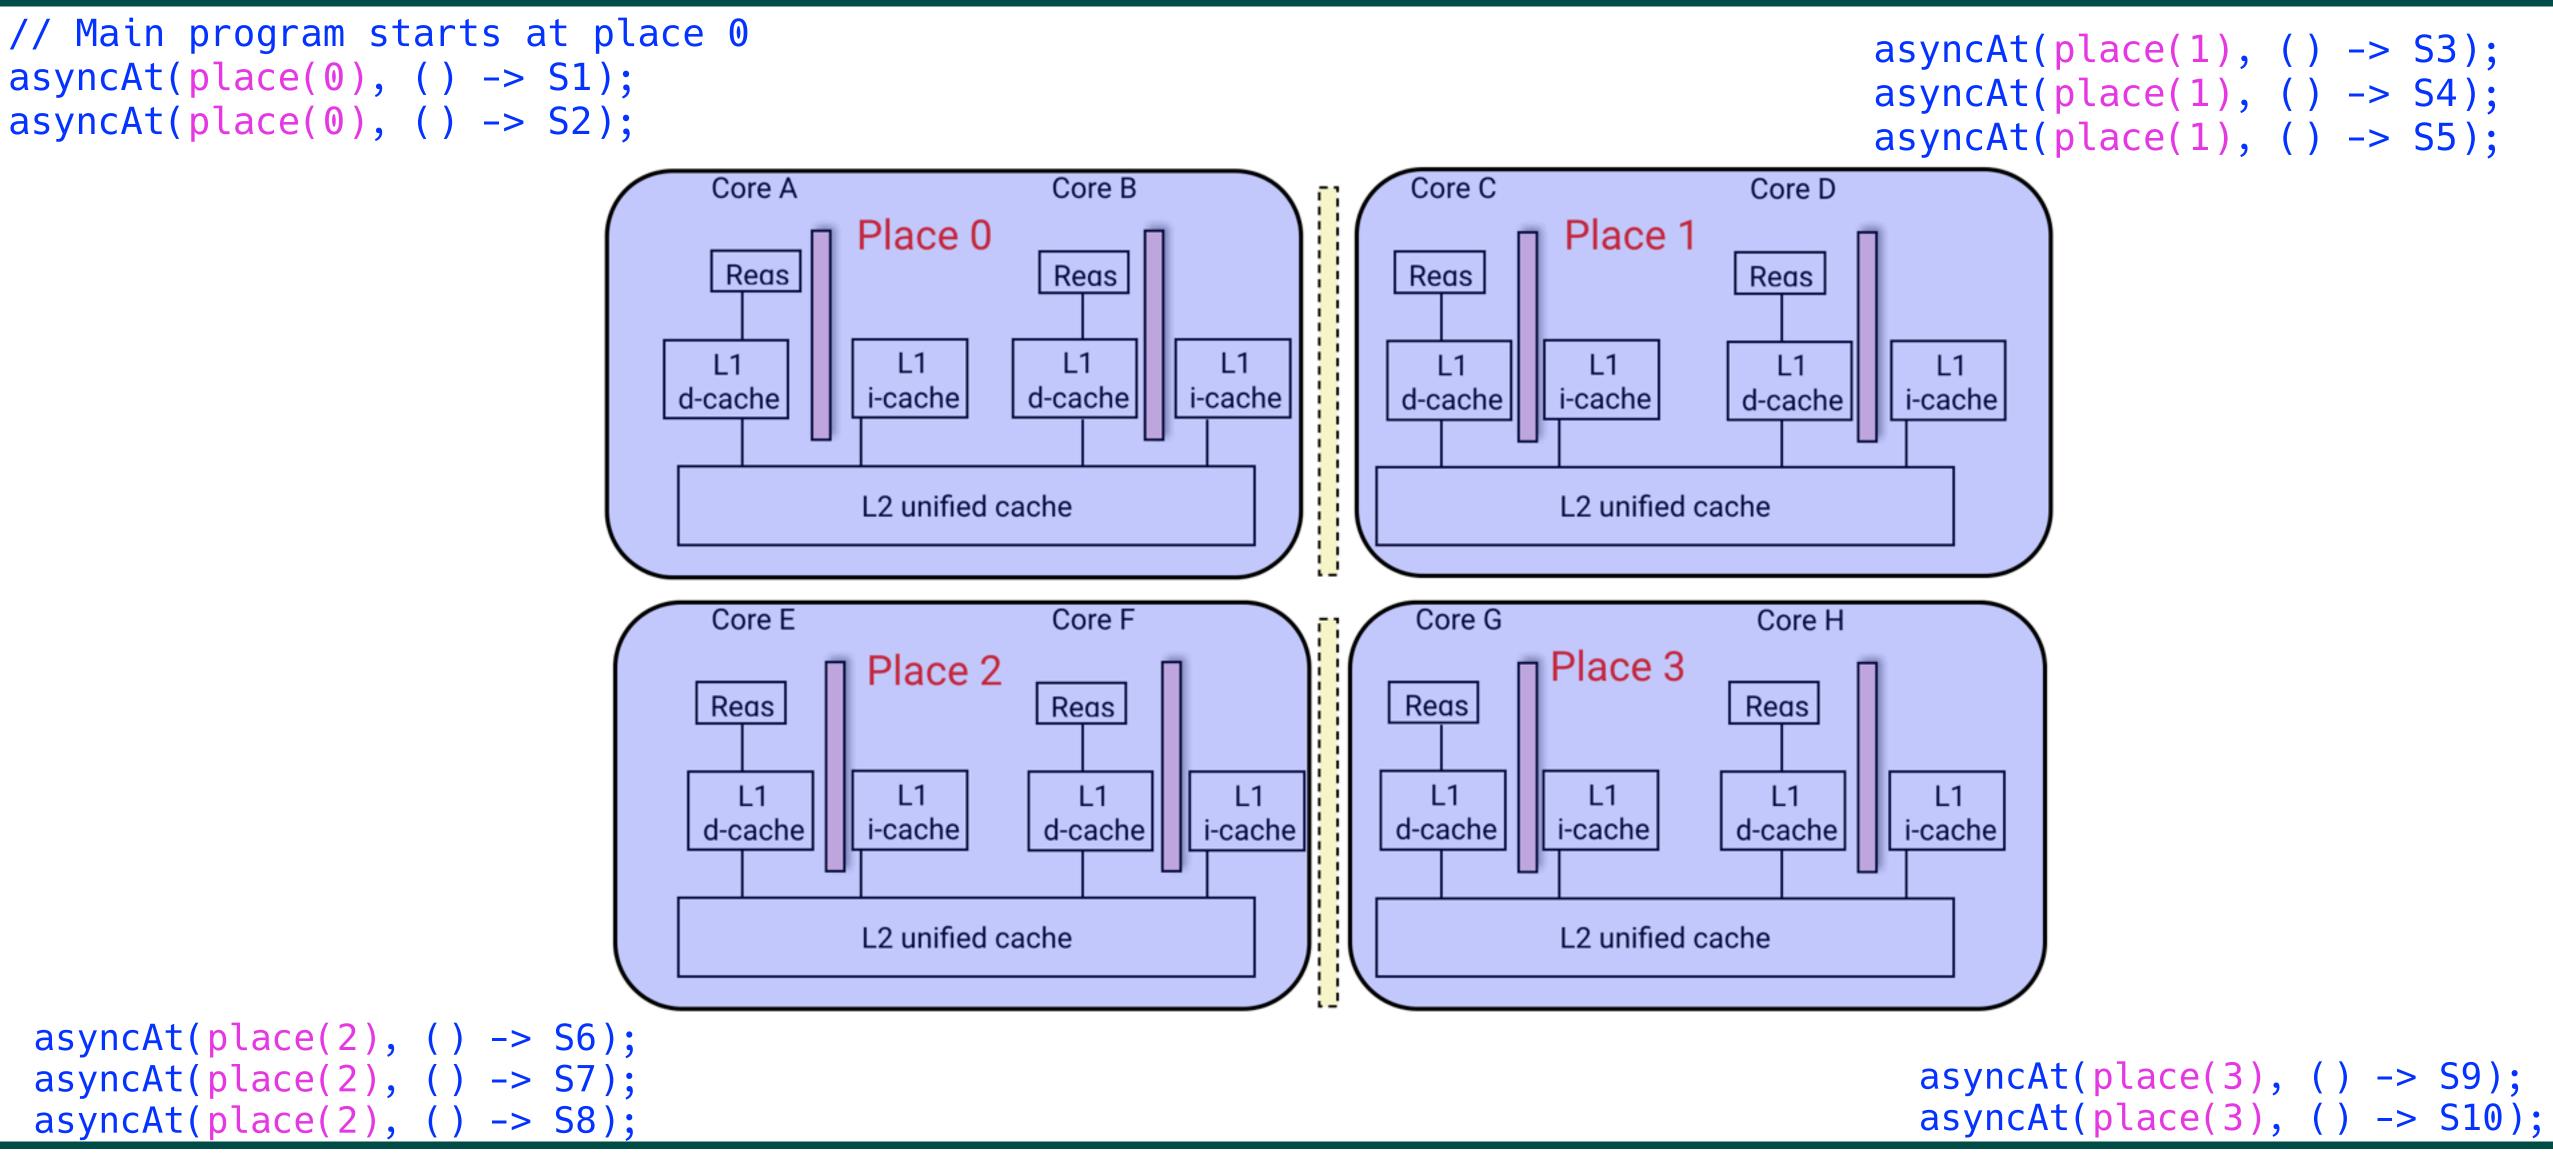

here() = place at which current task is executing numPlaces() = total number of places (runtime constant) Specified by value of p in runtime option: HjSystemProperty.numPlaces.set(p); place(i) = place corresponding to index i<place-expr>.toString() returns a string of the form "place(id=0)" <place-expr>.id() returns the id of the place as an int $asyncAt(P, () \rightarrow S)$

- Creates new task to execute statement S at place P async(() -> S) is equivalent to asyncAt(here(), () -> S)
- Main program task starts at place(0)

Note that here() in a child task refers to the place P at which the child task is executing, not the place where the parent task is executing

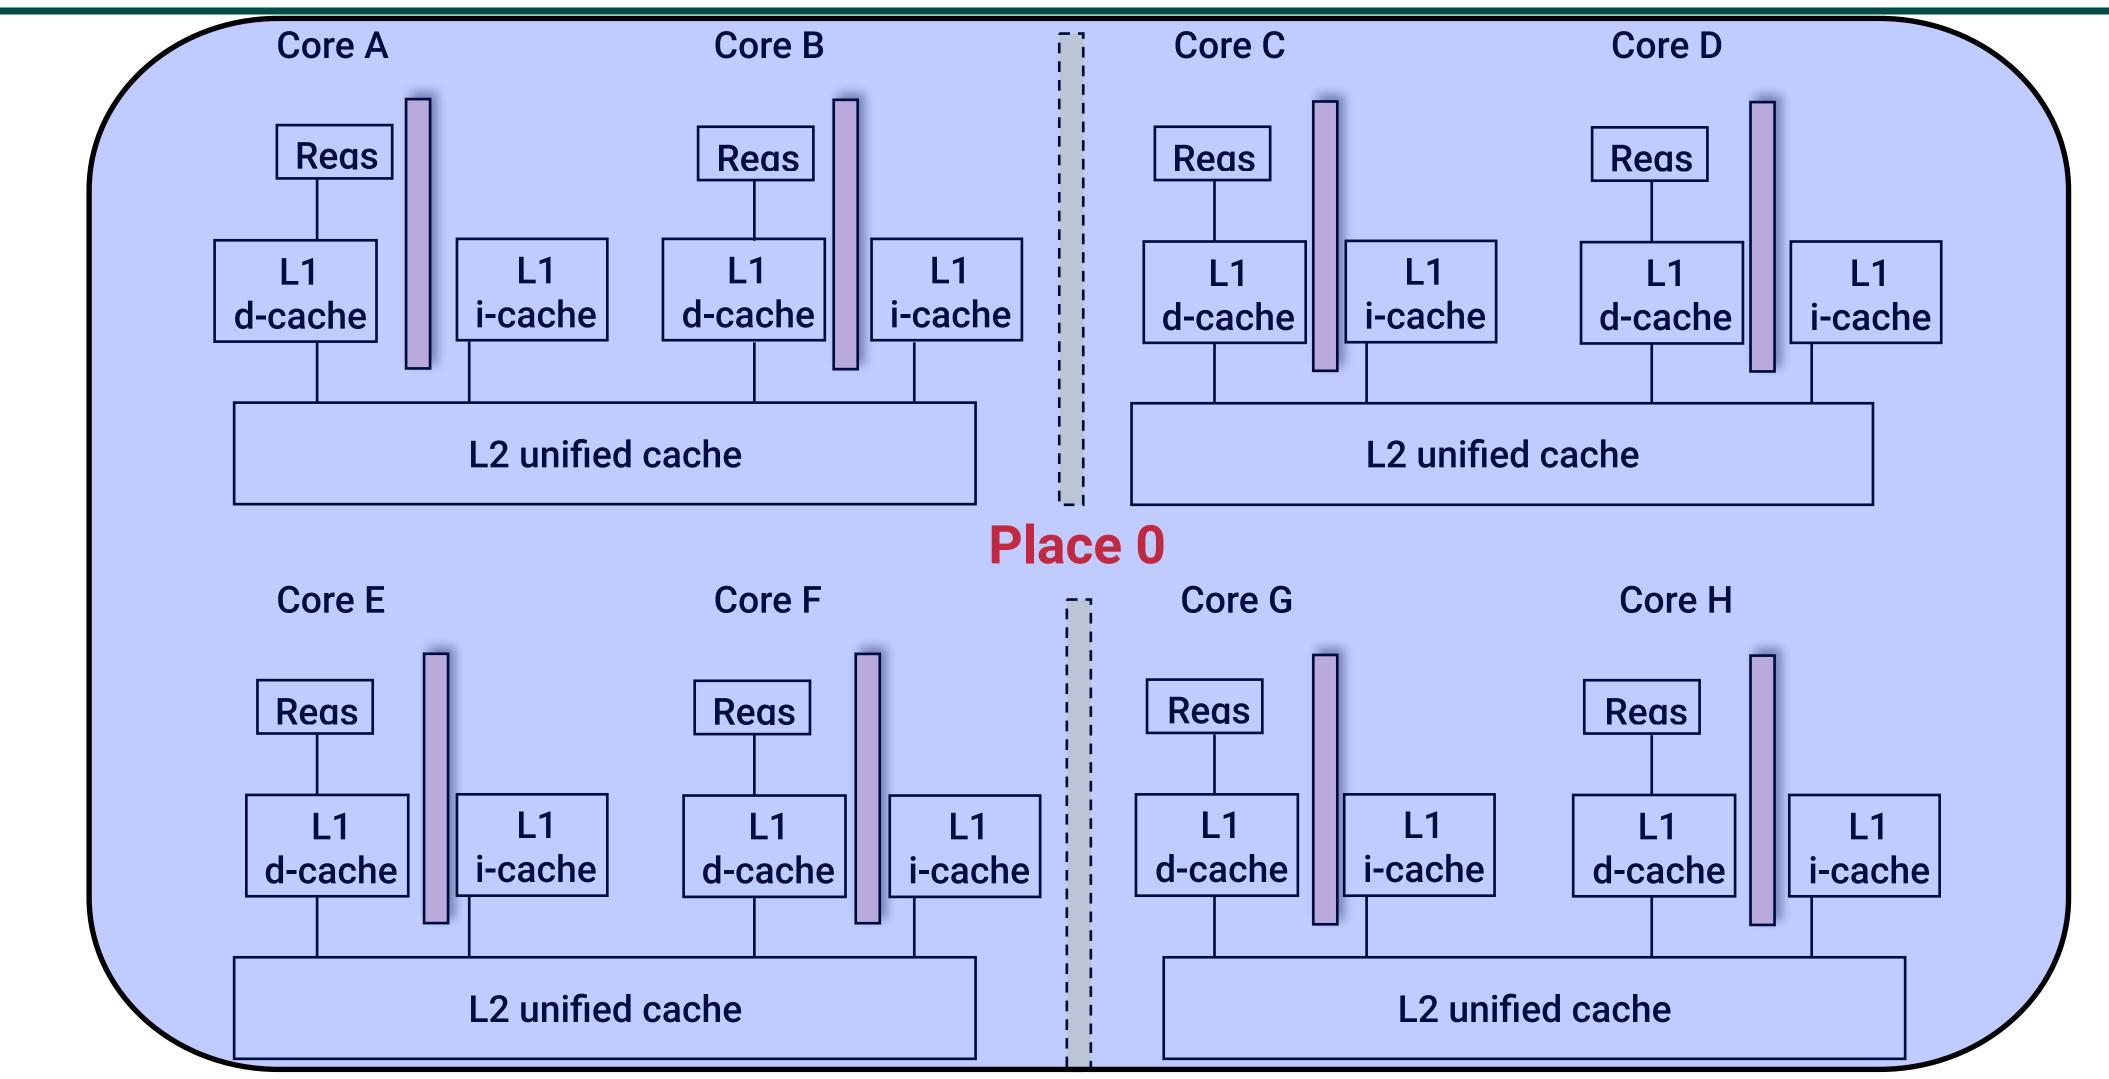

Example of 4:2 option on an 8-core node (4 places w/ 2 workers per place)

Example of 1:8 option (1 place w/ 8 workers per place)

All async's run at place 0 when there's only one place!

```
private static class T1 {
1.
      final HjPlace affinity;
2.
      public T1(HjPlace affinity) {
4.
        // set affinity of instance to place where it is created
5.
        this.affinity = here();
6.
7.
        • • •
8.
      }
      public void foo() { ... }
9.
10. }
11.
   finish(() -> {
12.
      println("Parent place: " + here());
13.
      for (T1 a : t10bjects) {
14.
        // Execute async at place with affinity to a
15.
        asyncAt(a.affinity, () -> {
16.
17.
          a.foo();
18.
        });
19.
20.
21. });
```

println("Child place: " + here()); // Child task's place

Chunked Fork-Join Iterative Averaging Example with Places

- public void runDistChunkedForkJoin(1. int iterations, int numChunks, Dist dist) { 2. // dist is a user-defined map from int to HjPlace 3. for (int iter = 0; iter < iterations; iter++) {</pre> 4. 5. finish(() -> { 6. forseq (0, numChunks - 1, (jj) \rightarrow { 7. asyncAt(dist.get(jj), () -> { 8. 9. 10. 11. }); 12. }); }); 13. double[] temp = myNew; myNew = myVal; myVal = temp; 14. } // for iter 15. 16. }
- Chunk jj is always executed in the same place for each iter

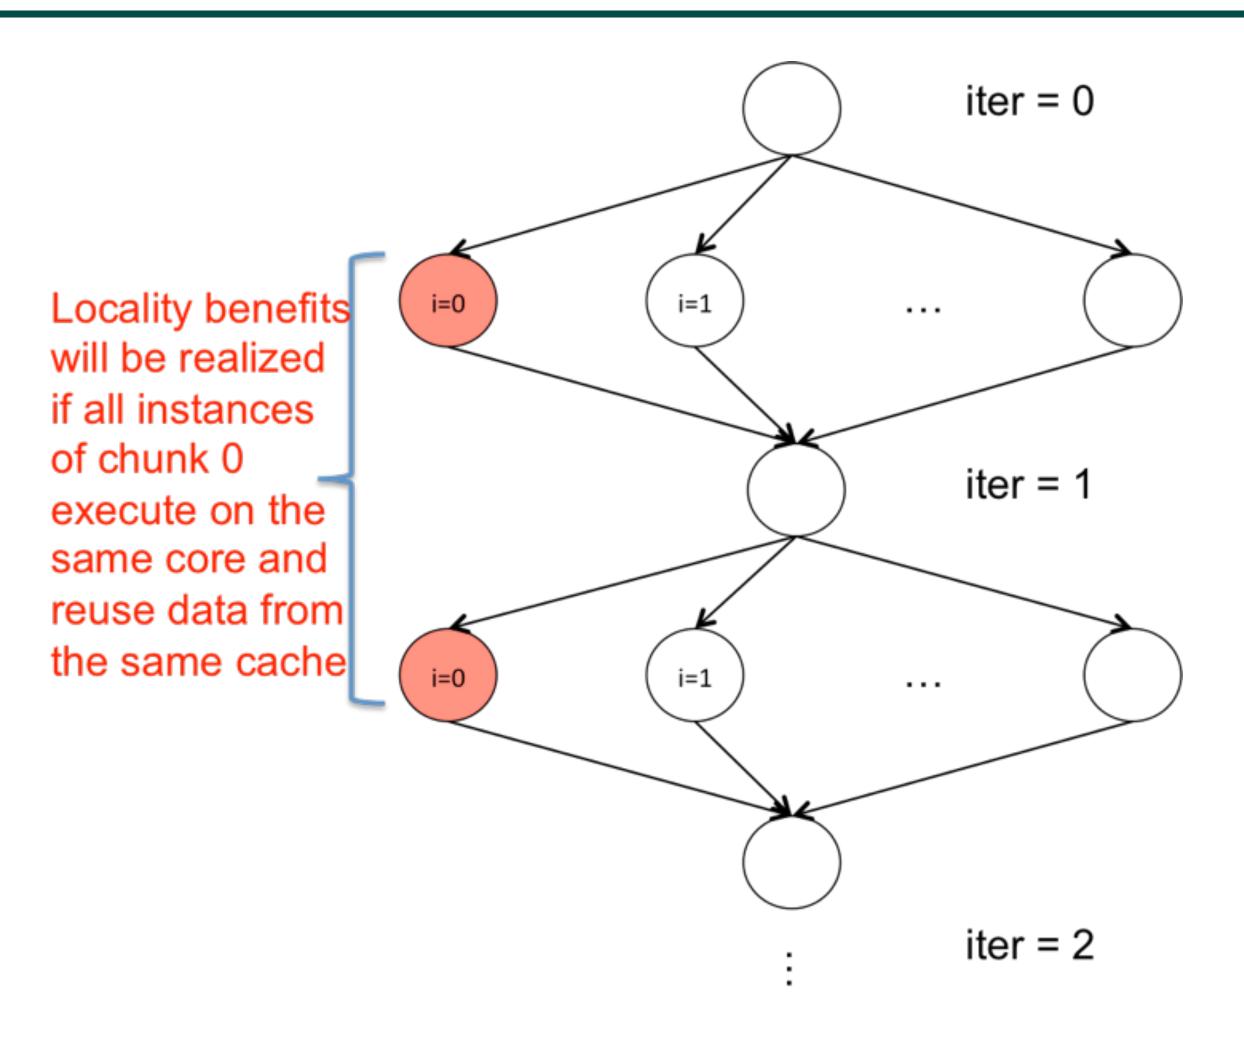

```
forseq (getChunk(1, n, numChunks, jj), (j) -> {
 myNew[j] = (myVal[j-1] + myVal[j+1]) / 2.0;
```

Method runDistChunkedForkJoin can be called with different values of distribution parameter d

Analyzing Locality of Fork-Join Iterative Averaging Example with Places

- A block distribution splits the index region into contiguous subregions, one per place, while trying to keep the subregions as close to equal in size as possible.
- Block distributions can improve the performance of parallel loops that exhibit spatial locality across contiguous iterations.
- Example: dist.get(index) for a block distribution on 4 places, when index is in the range, 0...15

Index	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Place id	0			1				2				3				

- by distribution d i.e., at place d.get(p).

```
finish {
      region r = ...; // e.g., [0:15] or [0:7,0:1]
 \mathbf{2}
      dist d = dist.factory.block(r);
 3
      for (point p:r)
 4
        async at(d.get(p)) {
 \mathbf{5}
           // Execute iteration p at place specified by distribution d
6
 \mathbf{7}
8
          finish
9
10
```

The pseudocode below shows the typical pattern used to iterate over an input region r, while creating one async task for each iteration p at the place dictated

This pattern works correctly regardless of the rank and contents of input region r and input distribution d i.e., it is not constrained to block distributions

- spanning the input region
- Cyclic distributions can improve the performance of parallel loops that exhibit load imbalance
- Example: dist.get(index) for a cyclic distribution on 4 places, when index is in the range, 0...15

Index	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Place id	0	1	2	3	0	1	2	3	0	1	2	3	0	1	2	3

A cyclic distribution "cycles" through places 0 ... place.MAX PLACES – 1 when

- Quiz for Unit 7 is due today at 11:59pm
- The entire written + programming (Checkpoint #2) is due by Wednesday, April 22nd at 11:59pm
- Quiz for Unit 8 will be available today and is due Friday, April 24th at 11:59pm

```
public void sampleKernel(
2.
        int iterations, int numChunks, Distribution dist) {
3.
      for (int iter = 0; iter < iterations; iter++) {</pre>
4.
        finish(() -> {
          forseq (0, numChunks - 1, (jj) \rightarrow \{
5.
            asyncAt(dist.get(jj), () -> {
6.
7.
              doWork(jj);
              // Assume that time to process chunk jj = jj units
8.
9.
          });
10.
         });
     });
11.
    } // for iter
12.
13. } // sample kernel
```

 Assume an execution with n places, each place with one worker thread • Will a block or cyclic distribution for dist have a smaller abstract completion time, assuming that all tasks on the same place are serialized with one worker per place?
