Worksheet #5: Computation Graphs for Async-Finish and Future Constructs

1) Can you write pseudocode with async-finish constructs that generates a Computation Graph with the same ordering constraints as the graph on the right? If so, provide a sketch of the program.

No. Finish cannot be used to ensure that D waits for both B and C, while E waits only for C.

2) Can you write pseudocode with future async-get constructs that generates a Computation Graph with the same ordering constraints as the graph on the right? If so, provide a sketch of the program.

Yes, see program sketch with void futures. A dummy return value can also be used.

Worksheet #5 solution (contd)

```
1. HjFuture<Void> A = future(() -> {
2.     return "A"; });
3. HjFuture<Void> B = future(() -> {
4.     A.get(); return "B"; });
5. HjFuture<Void> C = future(() -> {
6.     A.get(); return "C"; });
7. HjFuture<Void> D = future(() -> {
8.     // Order of B.get() & C.get() doesn't matter
9.     B.get(); C.get(); return "D"; });
10. HjFuture<Void> E = future(() -> {
11.     C.get(); return "E"; });
12. HjFuture<Void> F = future(() -> {
13.     D.get(); E.get(); return "F"; });
14. F.get();
```

Background: Functional Programming

- Eliminate side-effects
 - emphasizes functions whose results that depend only on their inputs and not on any other program state
 - calling a function, $f(x)$, twice with the same value for the argument x will produce the same result both times

Helpful Link: http://en.wikipedia.org/wiki/Functional_programming

Example: Binomial Coefficient

- The coefficient of the x^k term in the polynomial expansion of the binomial power $(1 + x)^n$
- Number of sets of k items that can be chosen from n items
- Indexed by n and k
 - written as $C(n, k)$
 - read as “ n choose k ”
- Factorial Formula: $C(n, k) = \left(\frac{n!}{k!(n-k)!} \right)$
- Recursive Formula
 $C(n, k) = C(n - 1, k - 1) + C(n - 1, k)$
Base cases: $C(n, n) = C(n, 0) = C(0, k) = 1$

Helpful Link: http://en.wikipedia.org/wiki/Binomial_coefficient

Example: Binomial Coefficient (Recursive Sequential version)

```
1. int choose(int N, int K) {
2.     if (N == 0 || K == 0 || N == K) {
3.         return 1;
4.     }
5.     int left  = choose (N-1, K - 1);
6.     int right = choose (N-1, K);
7.     return left + right;
8. }
```

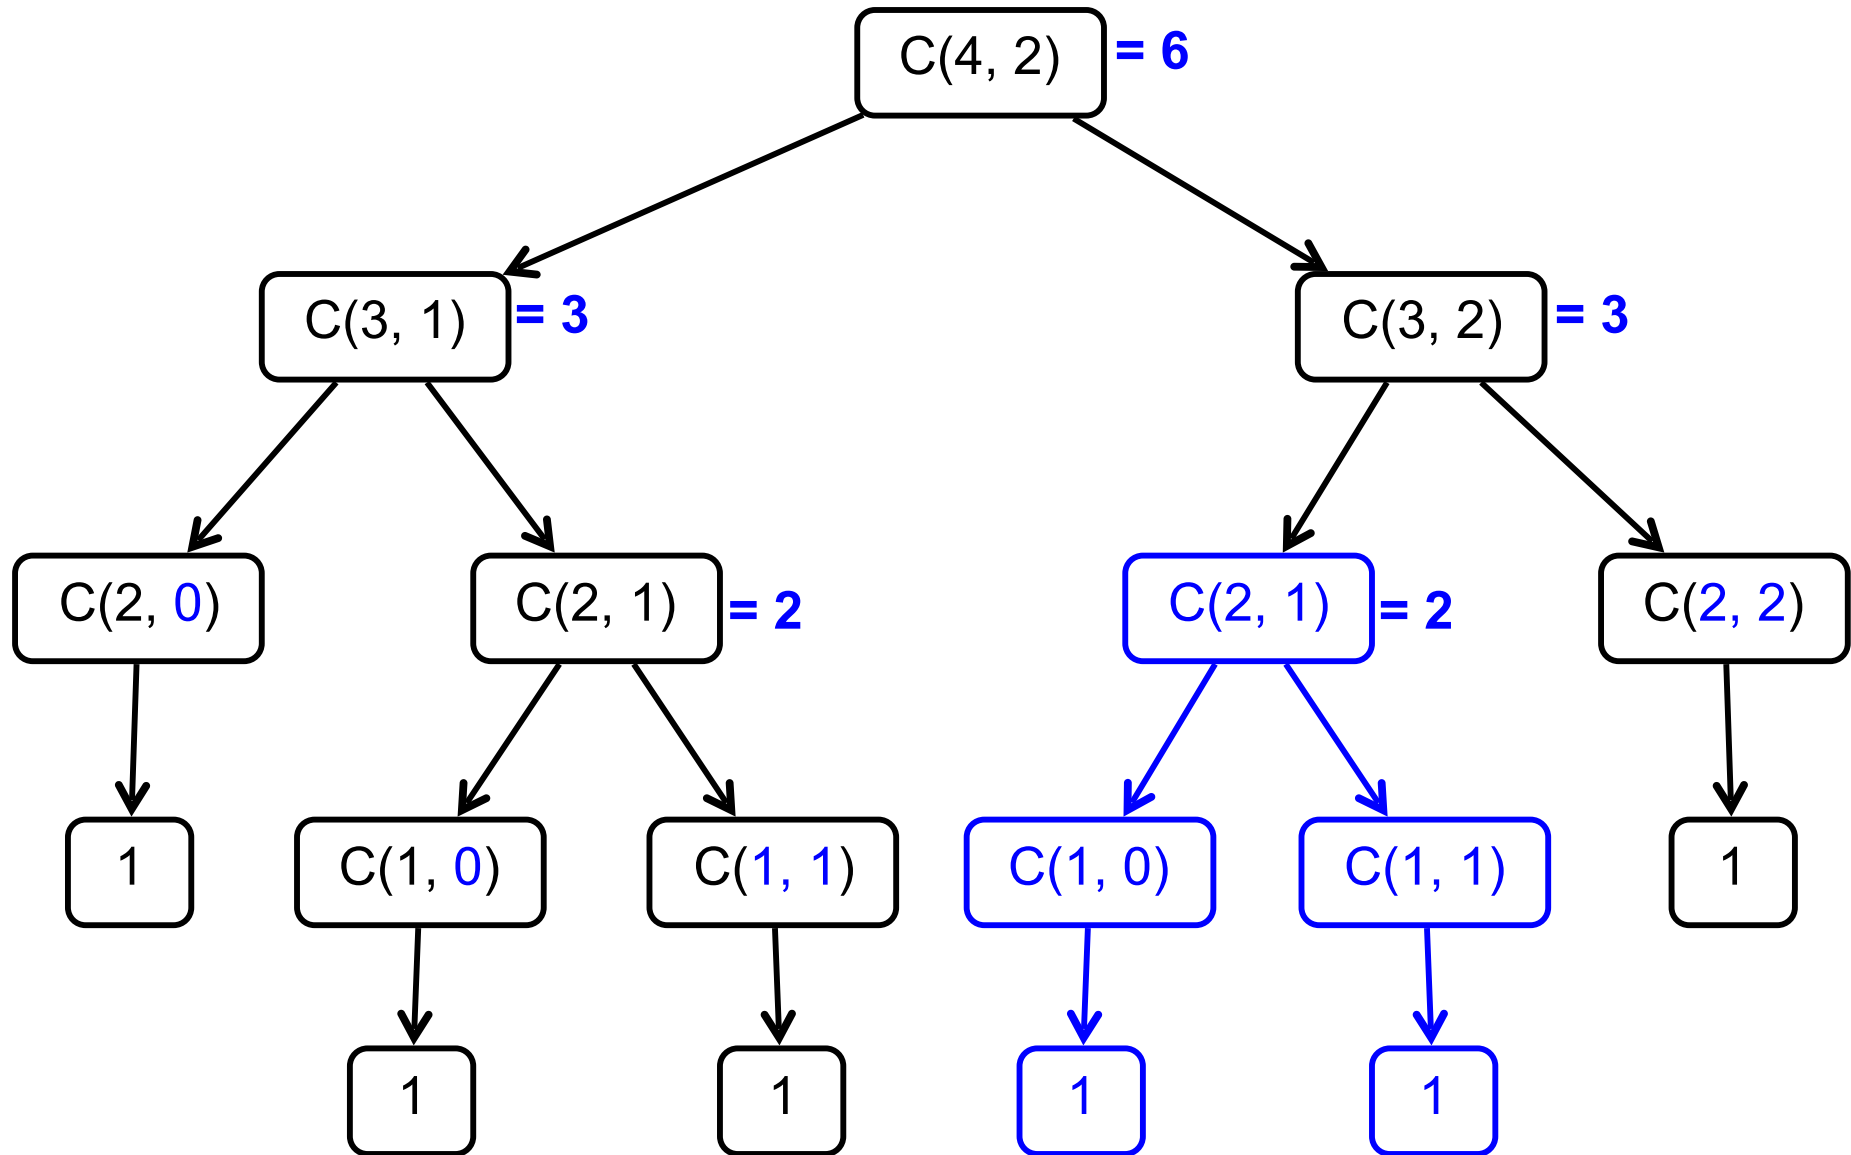

Example: Binomial Coefficient (Parallel Recursive Pseudocode)

```
1. int choose(int N, int K) {
2.     if (N == 0 || K == 0 || N == K) {
3.         return 1;
4.     }
5.     future<int> left =
6.         future { return choose (N-1, K-1); }
7.     future<int> right =
8.         future { return choose (N-1, K); }
7.     return left.get() + right.get();
8. }
```

- Use of futures supports incremental parallelization with low developer effort

What inefficiencies do you see in the recursive Binomial Coefficient algorithm?

Memoization

- Memoization - saving and reusing previously computed values of a function rather than recomputing them
 - A optimization technique with space-time tradeoff
- A function can only be memoized if it is *referentially transparent*, i.e. functional
- Related to caching
 - memoized function "remembers" the results corresponding to some set of specific inputs
 - memoized function populates its cache of results transparently on the fly, as needed, rather than in advance

Helpful Link: <http://en.wikipedia.org/wiki/Memoization>

Pascal's Triangle is an example of Memoization

$$C(n, k) = C(n - 1, k - 1) + C(n - 1, k)$$

Example: Binomial Coefficient (sequential memoized version)

```
1. final Map<Pair<Int, Int>, Int> cache = new ...;

2. int choose(int N, int K) {
3.     Pair<Int, Int> key = Pair.factory(N, K);
4.     if (cache.contains(key)) {
5.         return cache.get(key);
6.     }
7.     if (N == 0 || K == 0 || N == K) {
8.         return 1;
9.     }
10.    int left  = choose (N - 1, K - 1);
11.    int right = choose (N - 1, K);
12.    int result = left + right;
13.    cache.put(key, result);
14.    return result;
15. }
```

Example: Binomial Coefficient (parallel memoized version w/ futures)

```
1. final Map<Pair<Int, Int>, Int> cache = new ...;
2. int choose(final int N, final int K) {
3.     final Pair<Int, Int> key = Pair.factory(N, K);
4.     if (cache.contains(key)) {
5.         return cache.get(key);
6.     }
7.     if (N == 0 || K == 0 || N == K) {
8.         return 1;
9.     }
10.    future<int> left = future { return choose(N - 1, K - 1); }
11.    future<int> right = future { return choose(N - 1, K); }
12.    int result = left.get() + right.get();
13.    cache.put(key, result);
14.    return result;
15. }
```

- Assumes availability of a “thread-safe” cache library, e.g., ConcurrentHashMap

Example: Binomial Coefficient (parallel memoized version w/ futures - better)

```
1. final Map<Pair<Int, Int>, future<Int>> cache = new ...;
2. int choose(final int N, final int K) {
3.     final Pair<Int, Int> key = Pair.factory(N, K);
4.     if (cache.contains(key)) {
5.         return cache.get(key).get();
6.     }
7.     future<Int> f = future {
7.         if (N == 0 || K == 0 || N == K) return 1;
8.         future<int> left = future { return choose (N-1, K-1); }
9.         future<int> right = future { return choose (N-1, K); }
12.        return left.get() + right.get();
13.    }
14.    cache.put(key, f);
15.    return f.get();
16. }
```

- Assumes availability of a “thread-safe” cache library, e.g., ConcurrentHashMap
