Homework 07 (Due 10:00am Friday, March 12, 2010)

Submit via Owl-Space

Preliminaries

This homework can be done using either the Elementary or Intermediate language level of DrJava. If you are comfortable with casting between primitive types, the Intermediate level is probably a better choice because it supports such casting operations. You can test these operations in the Interactions pane, which supports the full Java language regardless of what language level is selected.

Composite Design Pattern for List

The following is an object-oriented formulation of lists of integers.

- `IntList` is an abstract list of `int`.
- `EmptyIntList` is an `IntList`
- `ConsIntList(first, rest)`, where `first` is an `int` and `rest` is an `IntList`, is an `IntList`

The above can be implemented in Java as follows.

```
/** Abstract list structure.  IntList := EmptyIntList + ConsIntList(int, IntList) */
abstract class IntList { }

/** Concrete empty list structure containing nothing. */
class EmptyIntList extends IntList { }

/** Concrete non-empty list structure containing an int, called first, and an IntList called rest. */
class ConsIntList extends IntList {
    int first;
    IntList rest;
}
```

The above implementation is an example of what is called the **Composite Design Pattern**. The composite design pattern is a special case of the union pattern where one or more of the variants for the union type `T` contains fields of root type `T`. In this pattern, the union is called a composite. Here the union type is `IntList` and the variant `ConsIntList` is said to be a composite because it includes a field of type `IntList`.

The composite pattern also prescribes a coding pattern for the its methods: when a variant is called to perform an operation, it traverses its fields of root type and calls on them to perform the same operation. It allows a client to treat an instance of type `T` and its embedded instances uniformly using polymorphism.

This coding pattern is called the interpreter design pattern: it interprets the abstract behavior of a class in each of its concrete subclasses. The composite pattern refers to the structure of the composite type hierarchy, while the interpreter pattern refers to how the behavior of the variants of the type are defined uniformly via polymorphism.

Interpreter Design Pattern for List

The interpreter design pattern applied to the above composite list structure prescribes a coding pattern for list operations that is analogous to Scheme function template. It entails declaring an abstract method for each list operation in the abstract list class, `IntList`, and defining corresponding concrete methods in the concrete list subclasses: the empty list class, `EmptyIntList`, and the non-empty class, `ConsIntList`. The concrete method for `EmptyIntList` corresponds to the base case in the Scheme function template while the concrete method in `ConsIntList` corresponds to the recursive case by calling the same method on its `rest`.

The following is the coding template for the interpreter design pattern for `IntList` and its subclasses.

```

abstract class IntList {
    abstract returnType methodName(parameter_list);
}

class EmptyIntList extends IntList {
    returnType methodName(parameter_list) {
        // base case code
    }
}

class ConsIntList extends IntList {
    int first;
    IntList rest;
    returnType methodName(parameter_list) {
        // ... first ...
        // ... rest.methodName(parameter_list) ...
    }
}

```

Problems

Apply the interpreter design pattern to `IntList` and its subclasses to write the following methods. Also write a JUnit test class to test all methods in `EmptyIntList` and a different JUnit test class to test all methods in `ConsIntList`. We strongly recommend that you write Template Instantiations as an intermediate step in developing your code **BUT DO NOT submit** these Template Instantiations (or corresponding Templates) as part of your code documentation. Confine your documentation to writing contracts (purpose statements in HTDP terminology) using javadoc notation. The javadoc documentation style will be discussed in the upcoming lab.

- (10 pts.) `boolean contains(int key)`: returns true if key is in the list, false otherwise.
- (10 pts.) `int length()`: computes the length of the list.
- (10 pts.) `int sum()`: computes the sum of the elements in the list.
- (10 pts.) `double average()`: computes the average of the elements in the list; returns 0 if the list is empty.
Hint: at the Intermediate level you can cast an `int` to `double` by using the prefix operator (`double`). At the Elementary level, casts are illegal, but you can use the workaround of adding `0.` to an `int` to convert it to `double`.
- (10 pts.) `IntList notGreaterThan(int bound)`: returns a list of elements in this list that are less or equal to `bound`.
- (10 pts.) `IntList remove(int key)`: returns a list of all elements in this list that are not equal to `key`.
- (10 pts.) `IntList subst(int oldN, int newN)`: returns a list of all elements in this list with `oldN` replaced by `newN`.
- (30 pts.) `IntList merge(IntList other)` merges this list with the input list `other`, assuming that this list and `other` are sorted in ascending order. Note that the lists need not have the same length.
Hint: add a method `mergeHelp(ConsIntList other)` that does all of the work if one list is non-empty (a `ConsIntList`). Only `mergeHelp` is recursive. Use dynamic dispatch on the list that may be empty. Recall that `a.merge(b)` is equivalent to `b.merge(a)`. This approach is the Java analog of the extra credit option in HTDP Problem 17.6.1 in HW 3.
